Chapter 1

Research Questions

The research seeks to answer the following questions:

1. Is there a relationship between working from home and employee motivation?
2. Is there a relationship between working from home and job satisfaction?
3. Is there a relationship between employee motivation and job satisfaction?
4. How do technological skills affect the relationship between employee motivation and job satisfaction when working from home?

Chapter 2

Data

We collected the data using an online survey of Wits University staff members. The survey captured data for 41 variables of interest that covered constructs for job satisfaction, employee motivation, technology, and demographic and personal data. The description of the variables is in the appendix.

The sampling frame consisted of all () staff members of the university in 2021. The survey resulted in 201 questionaires for a desired sample size of 354. To make up for the defficiency, we bootstrapped the data to represent 354 observations. The rest of the analysis draws from these 354 observations.

2.1 Data Reliability

As noted in the methodology section, we used a virtual questionaire to collect the data from the administrative staff of University of the Witwatersrand, Johannesburg. In this ection, we examine the reliability of the data using the Cronbach's Alpha. The Cronbach's Alpha is useful for quantifying reliability of the data by measuring the internal consistency of the data.

```
Cronbach's alpha for the 'my_data' data-set

Items: 56
Sample units: 354
alpha: 0.219

Bootstrap 95% CI based on 1000 samples
 2.5% 97.5%
0.168 0.264
```

```
Cronbach's alpha for the 'my_data %>% dplyr::select(starts_with("motiv"))' data-set

Items: 9
Sample units: 354
alpha: 0.636
```

```
Bootstrap 95% CI based on 1000 samples
 2.5% 97.5%
0.573 0.686
```

```
Cronbach's alpha for the 'my_data %>% dplyr::select(starts_with("js"))' data-set

Items: 9
Sample units: 354
alpha: 0.303

 2.5% 97.5%
0.001 0.339
```

The Cronbach's $$ lies between 0.4 and 0.57 which may indicate poor response. For instance, most of the respondents are female and relatively older. However, the data does lie in the acceptable region.

2.2 Exploring the Data

We start this section by exploring the data set through visualizations. Figure 1 contains the profiles of employees in the sample and that responded to the survey. In Panel C, for instance, 84% of the respondents were female and 16% male. This response profile is problematic given that the sampling frame is different as the University has about 50% male employees []. Even more extreme is the profile for permanent versus part time employees at 93% and 7% (see Panel A), respectively, although this closely follows employee job categories at the University. The profiles for other employee categories including age, experience, marital status, and education level do not possess these extreme qualities. In the regression analysis, we control for the gender of the respondents (see section ()).

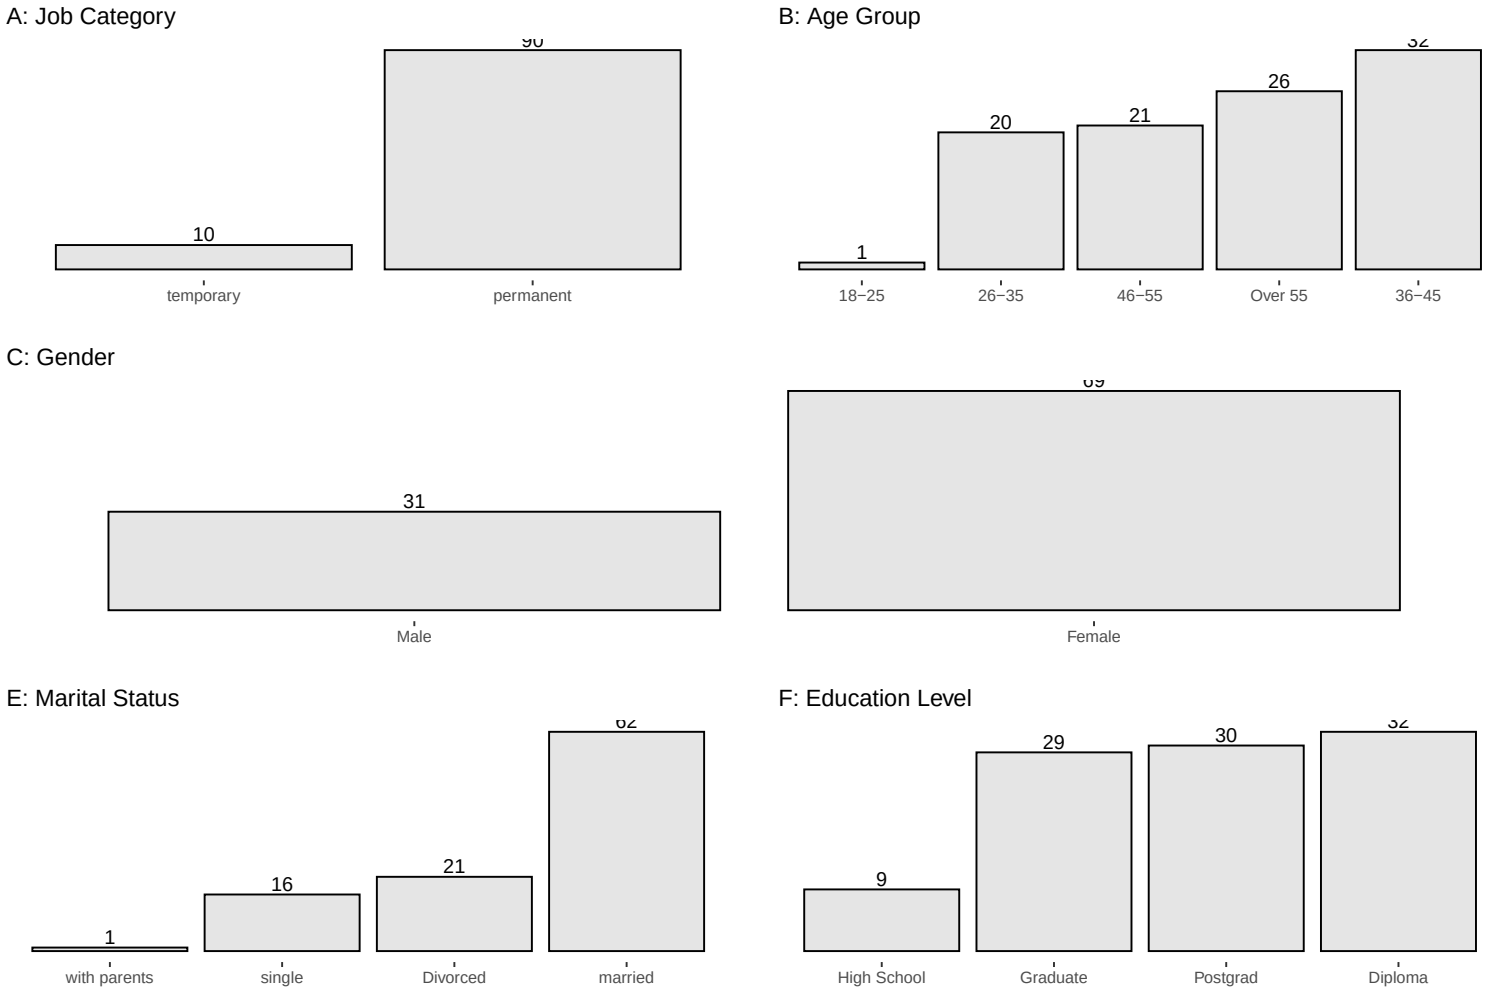

Figure 2.1: Respondents Profile (% of Total Count)

We also examine each of the categories of questions in the questionaire that covered the following areas.

- Motivation.
- Job Satisfaction.
- Working from home.
- Technology.

2.2.1 Motivation

Table () below shows the summary statistics of the responses capturing motivation of employees. On a scale of 1 (strongly disagree) to 7 (strongly agree), most respondents (102) strongly disagreed that they had no time to work when working from home (see the median od the variable motiv_no_time_to_work in the table). The other variables have a similar interpretation.

Table 2.1: Summary: Variables Capturing Motivation

Variable	Mean	SD	Min	Q1	Median	Q3	Max
motiv_enough_time_to_work	3.30	2.14	1	2	2	5	7
motiv_work_clearly_explained	3.93	2.27	1	2	4	6	7

motiv_comfortable_work_environment	5.51	1.81	1	5	6	7	7

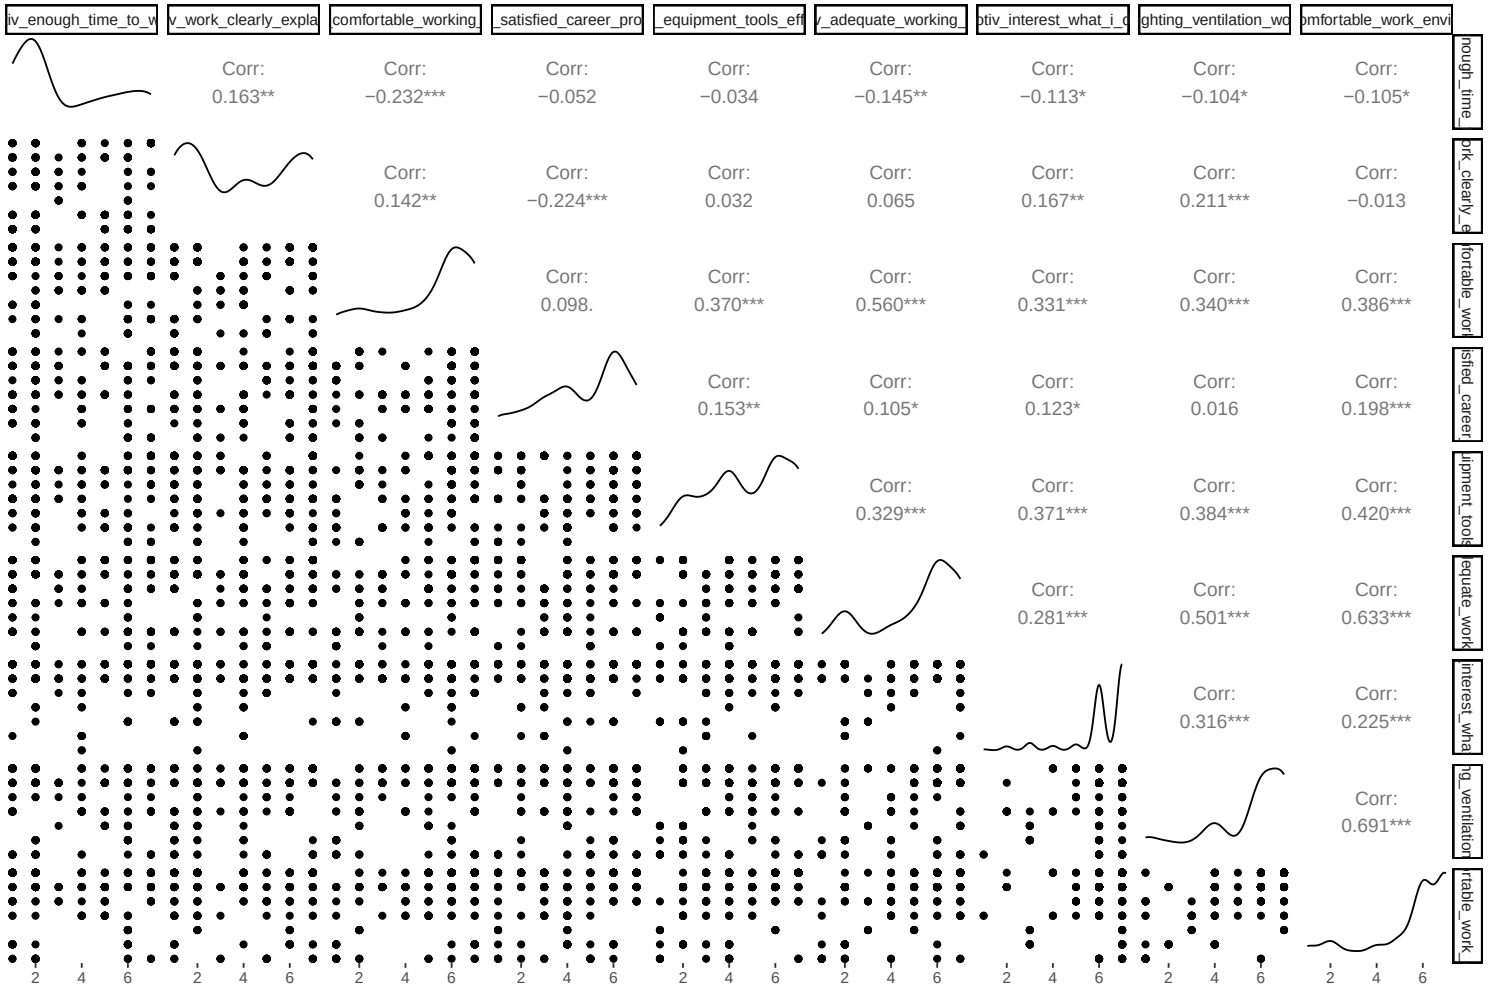

Figure 2.2: Correlation Between Motivation Indicators

2.2.2 Job satisfaction

Table () summarises the responses capturing job satisfaction. As an example, when the researcher posed the question "My day never seemed to end", most respondents strongly disagreed, implying a high degree of job satisfaction.

Table 2.2: Summary: Variables Capturing Motivation

Variable	Mean	SD	Min	Q1	Median	Q3	Max
js_day_seemed_to_never_end	4.21	1.99	1	2	4	6.00	7

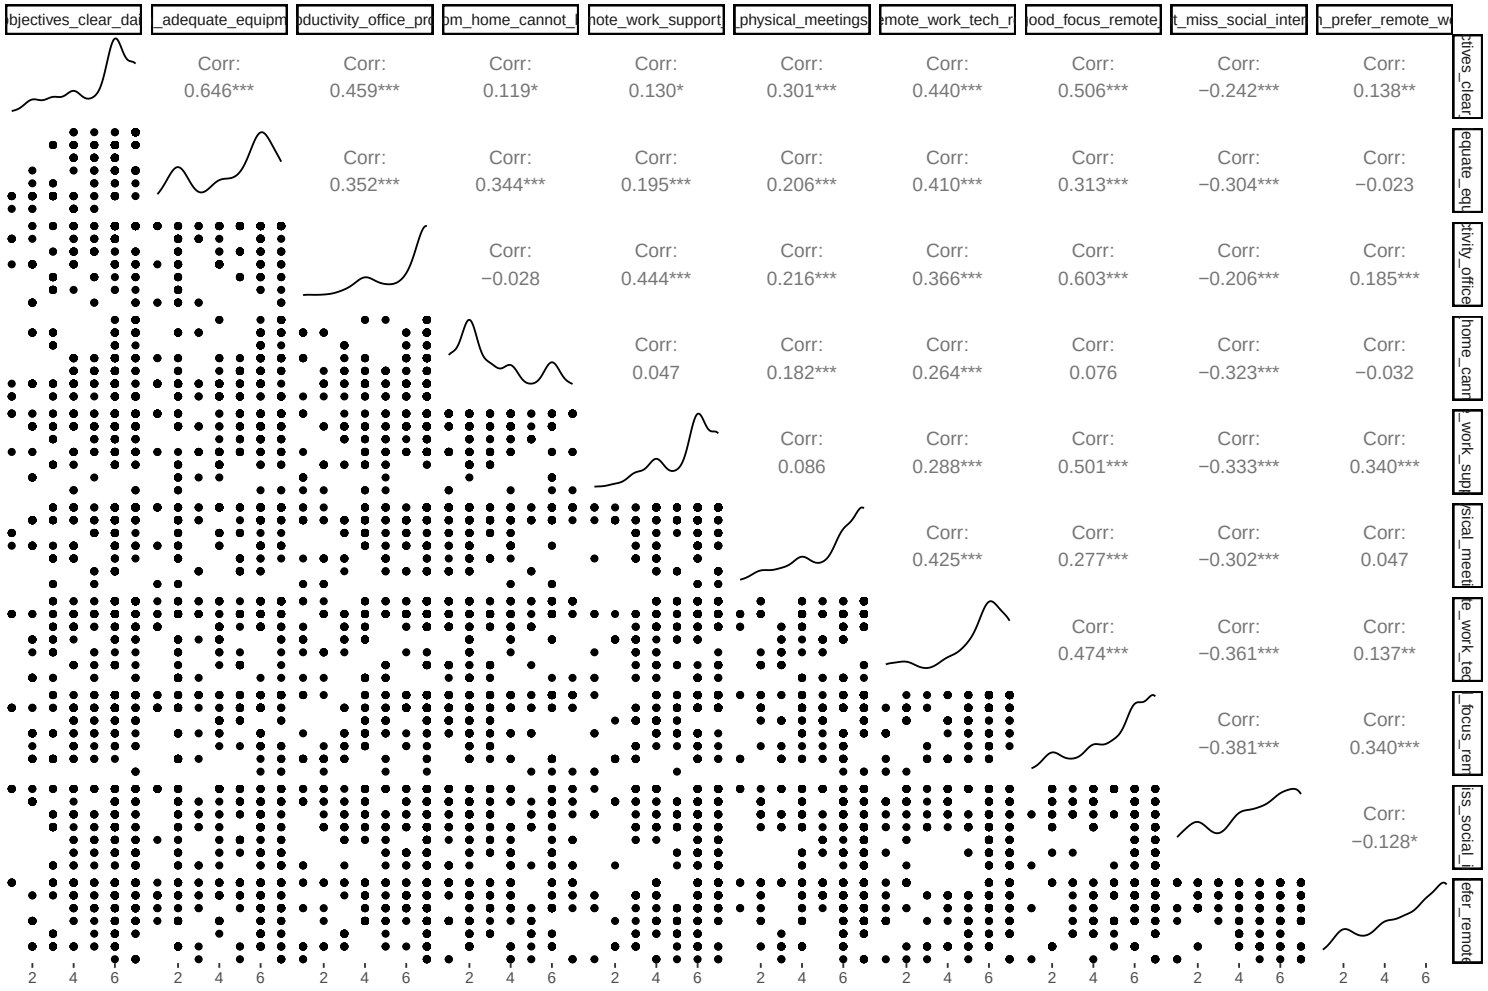

Figure 2.4: Correlation Between Working from Home Indicators

2.2.4 Technology

In this section, I visualize the variables that capture the use of technology by employees while working from home. As an example, most employees disagreed that they had problems communicating with colleagues virtually.

```
< table of extent 0 >
```

Table 2.4: Summary: Variables Capturing Technology

Variable	Mean	SD	Min	Q1	Median	Q3	Max
tech_communication_employees_easy	4.89	1.62	1	4	5	6	7

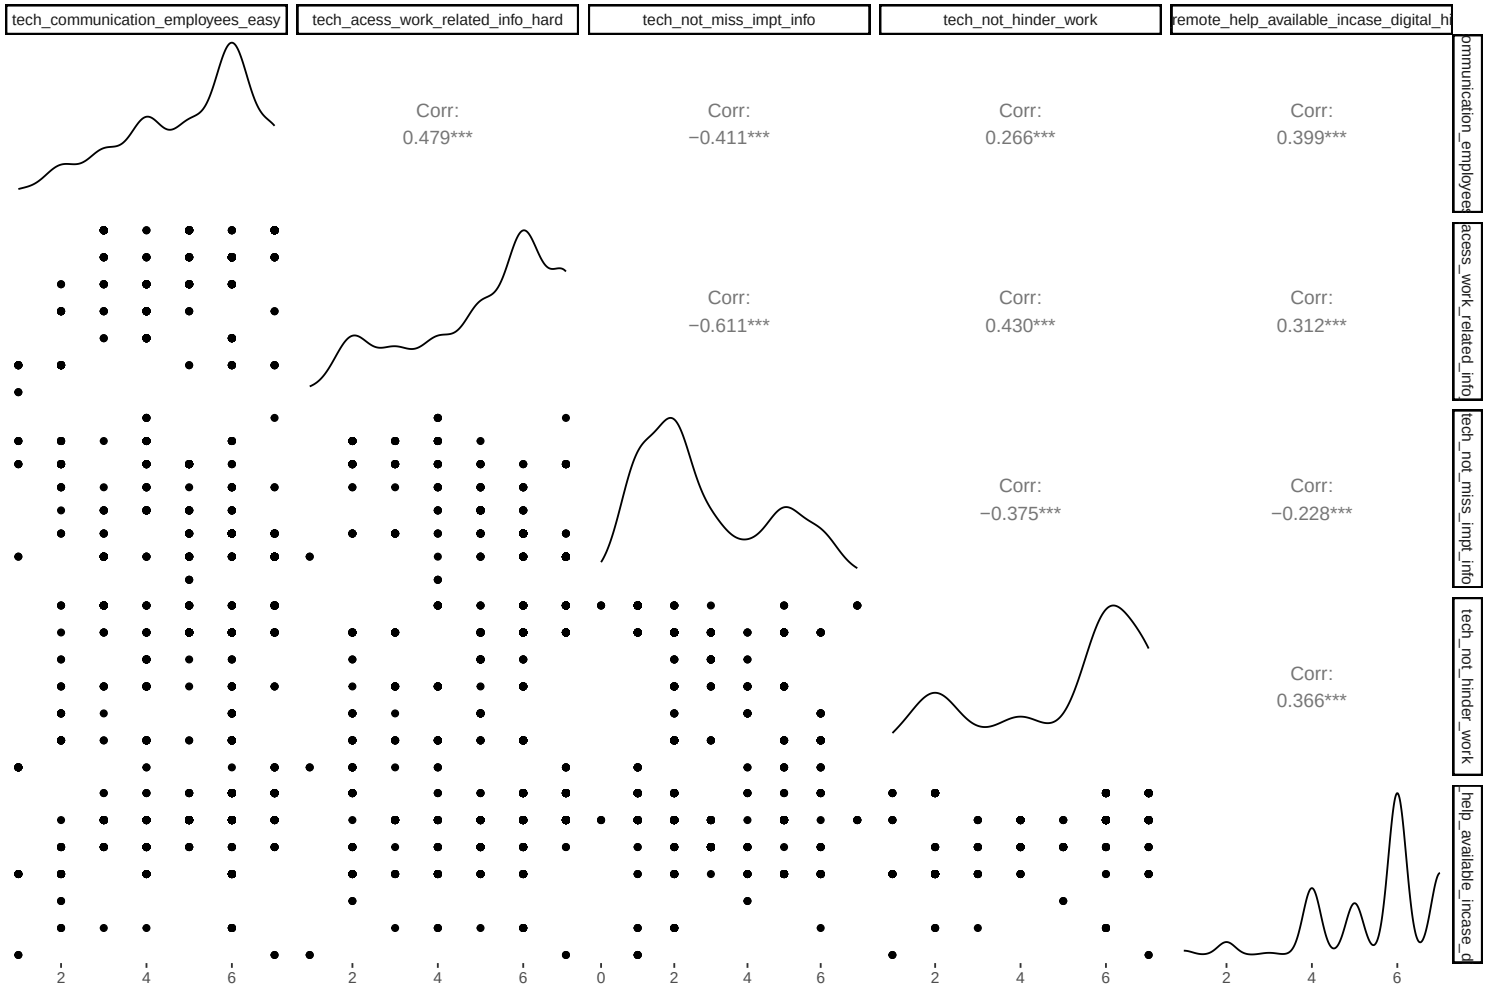

Figure 2.5: Correlation Between Working from Home Indicators

2.3 Data Analysis and Discussion of Results

In this section, we will examine the research questions in greater detail.

2.3.1 *Principal Components Analysis*

To start with, we create aggregate metrics to capture the four variables;

- Motivation.
- Job Satisfaction.
- Working from Home.
- Technology.

To construct these variables from the responses in the questionaires, we use the simple average. We label these variables `motiv` for motivation, `js` for job satisfaction, `wfh` for working from home, and `tech` for technology.

The output below shows the computation of each variable as the simpe arithmetic average of the responses.

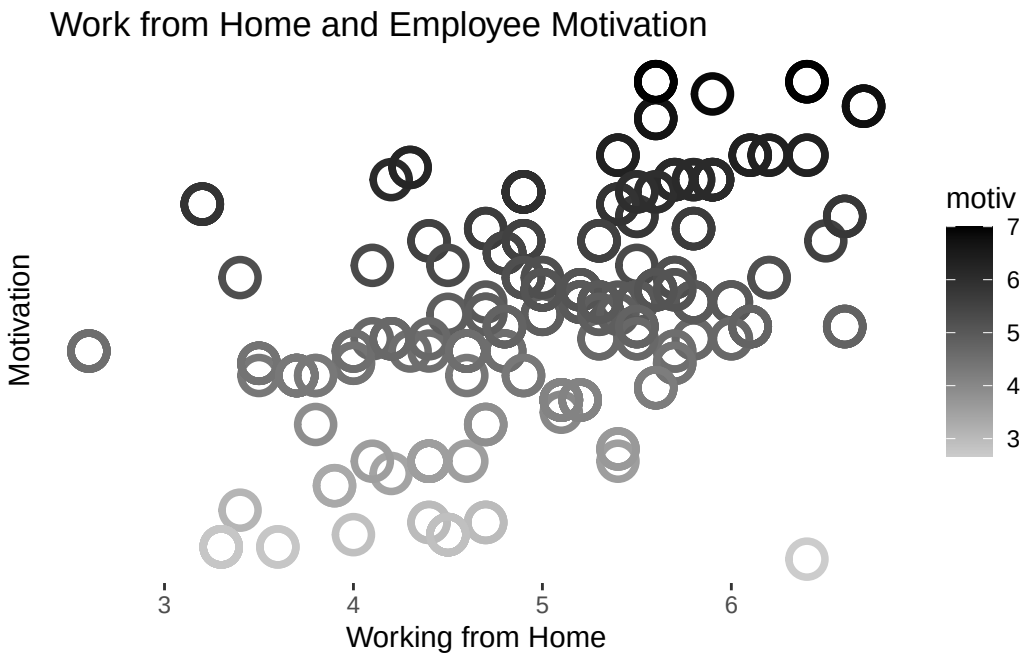
2.3.2 *Remote work and employee motivation?*

Figure () below shows the relationship between employee motivation and working from home. The relationship is negative at the initial levels but turns positive at higher levels. In the regression analysis in section () below, we examine the significance of the relationship between employee motivation and working from home in the presence of other related variables.

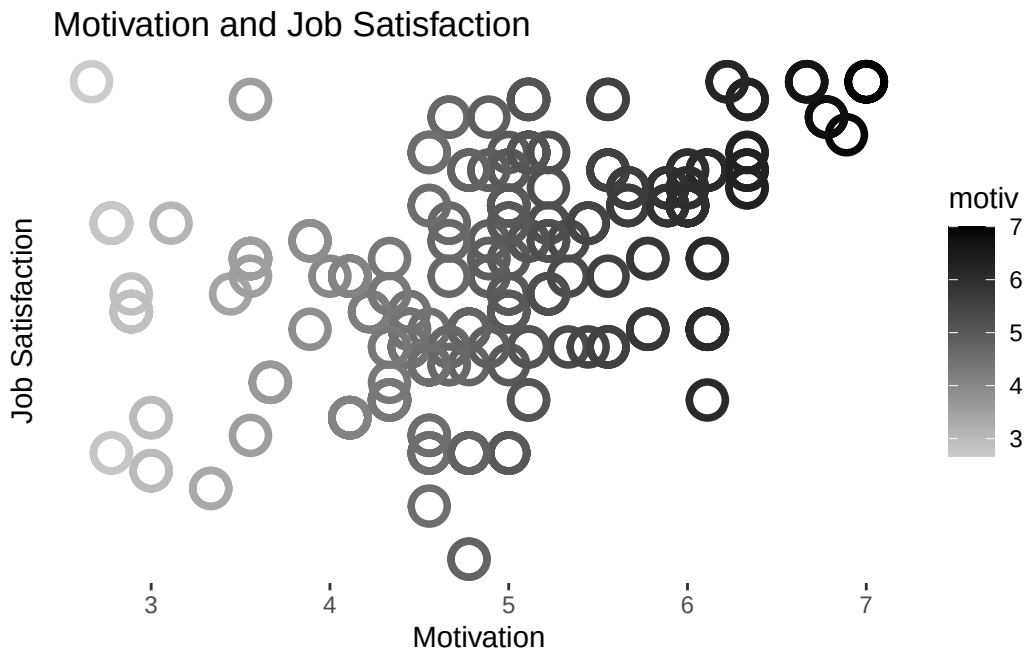


2.3.3 *Remote work and and job satisfaction?*

Figure () below shows the relationship between job satisfaction and working from home. The relationship is negative at the initial levels but flattens at higher levels. This observation goes against the theory. In the regression analysis in section () below, we examine the significance of this relationship in the presence of other related variables.

2.3.4 *Employee motivation and job satisfaction?*

As expected, Figure () below shows the positive relationship between employee motivation and job satisfaction. In line with the theory, higher employee motivation corresponds to higher job satisfaction. Again , we examine the significance of this relationship in the regression analysis section below.



2.3.5 *Technological skills, employee motivation and job satisfaction in remote work*

Overall, there is a positive relationship between the employee motivation and job satisfaction (see Figure () below). The figure also indicates that employees with better technology skills have higher motivation. However, job satisfaction does not appear to have a significant relationship with the technology. The implication here is that the positive relatonship between the employee motivation and job satisfaction arises from other factors beyond profficiency in technology. We discuss some of these other factors in the regression analysis in the next section.

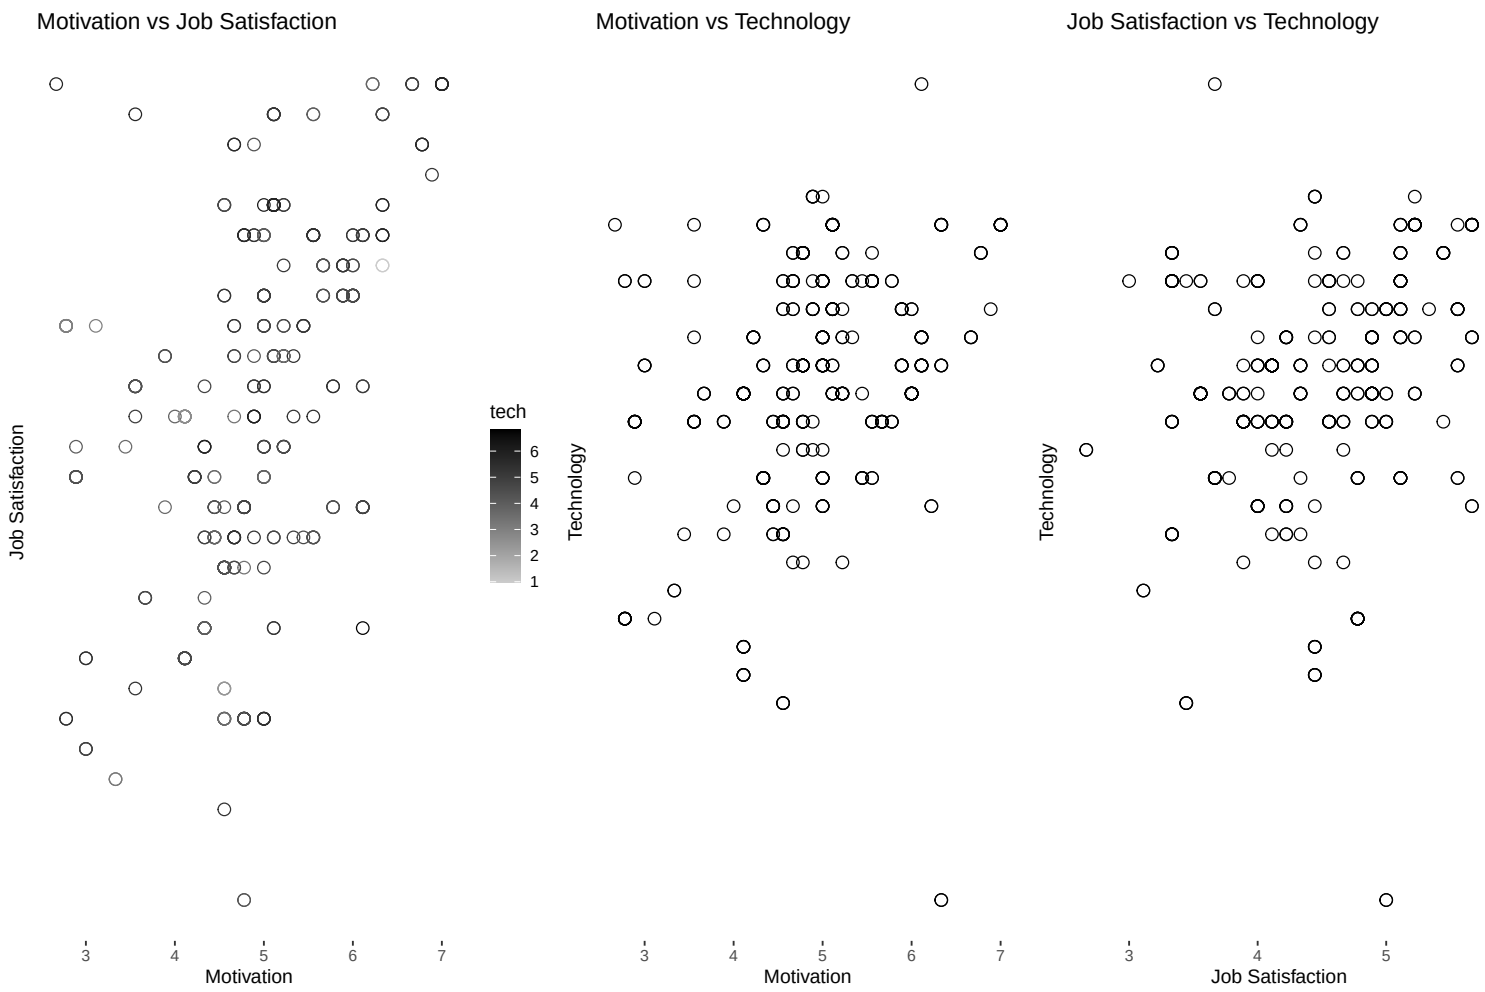


Figure 2.6: Respondents Profile (% of Total Count)

We run a regression analysis of the following form;

$motivation = {}_0 + {}_1 job_satisfaction + {}_n controls + error_term$

Where motivation and job_satisfaction are variables that captures employee motivation and job satisfaction, respectively. The controls include gender, age group, marital status, education level, employment category, experience, and whether or not the employee worked from home. We also include an interaction of technology and job satisfaction. The interaction is the outcome of interest in this section. The summary of the regression analysis is in the table below.

The regression confirms the outcome of Figure () above. While the relationship between job satisfaction and motivation is positive and significant, the relationship between motivation and the interaction of job satisfaction and technology is not. What are the additional variables that affect the levels of motivation among employees?

The regression table shows that the level of motivation among employees is a function of other variables. These variables include working from home (wfh), age group, marital status, education level, experience. Notably, both technology and job satisfaction are not a significant driver of the level of motivation among employees. However, the flexibility to work from home does positively affect the level of motivation.

Divorced employees had a greater motivation than married or single employees in the sample. Employees with certificate level education had less motivation compared to employees with higher levels of education. Part-time employees have a greater motivation motivation than parmanent employees which is a suprising outcome from the analysis.

Compared to employees with 1-5 years of experience, employees with experience between 6 and 20 years have a greater motivation. On the other hand, employees with experience of 21-25 years have significantly less motivation. Critically, working from home has a significant relationship with employee motivation. Hence, management could explore mechanisms to allow employees to choose remote work where possible.

Note that we do not include age in the regression as it is highly correlated with experience. The regression disagnostics plot in Figure () indicates a mild level of multicollinearity. However, the model is significant with the independent variables explaining 77% of the variation in the dependent variable with a significant F-statistic.

2.4 Robustness tests

Instead of using the median, we use the median intead of the mean to compute.

To construct these variables from the responses in the questionaires, we use the median for every response. We label these variables `motiv` for motivation, `js` for job satisfaction, `wfh` for working from home, and `tech` for technology.

The output below shows the computation of each variable as the simpe arithmetic average of the responses.

Next, we rerun the regressions. This time, we run the ordinal multinomial regression analysis.

$= {}_0 + {}_1 + {}_2 + {}_3 \ + {}_4 +$

2.5 Regression Diagnostics

For each of the models 1 to 4, we run the regression diagnostics.
